Background

Background	This gene encodes a member of the cysteine-aspartic acid protease (caspase) family. Sequential
	activation of caspases plays a central role in the execution-phase of cell apoptosis. Caspases exist
	as inactive proenzymes composed of a prodomain, a large protease subunit, and a small protease
	subunit. Activation of caspases requires proteolytic processing at conserved internal aspartic
	residues to generate a heterodimeric enzyme consisting of the large and small subunits. This
	protein is involved in the programmed cell death induced by Fas and various apoptotic stimuli. The
	N-terminal FADD-like death effector domain of this protein suggests that it may interact with Fas-
	interacting protein FADD. This protein was detected in the insoluble fraction of the affected brain
	region from Huntington disease patients but not in those from normal controls, which implicated the
	role in neurodegenerative diseases. Many alternatively spliced transcript variants encoding
	different isoforms have been described, although not all variants have had their full-length
	sequences determined. [provided by RefSeq, Jul 2008]
