## Background

Background	This gene was identified as a tumor suppressor that is mutated in a large number of cancers at
	high frequency. The protein encoded by this gene is a phosphatidylinositol-3,4,5-trisphosphate 3-
	phosphatase. It contains a tensin like domain as well as a catalytic domain similar to that of the
	dual specificity protein tyrosine phosphatases. Unlike most of the protein tyrosine phosphatases,
	this protein preferentially dephosphorylates phosphoinositide substrates. It negatively regulates
	intracellular levels of phosphatidylinositol-3,4,5-trisphosphate in cells and functions as a tumor
	suppressor by negatively regulating AKT/PKB signaling pathway. The use of a non-canonical
	(CUG) upstream initiation site produces a longer isoform that initiates translation with a leucine,
	and is thought to be preferentially associated with the mitochondrial inner membrane. This longer
	isoform may help regulate energy metabolism in the mitochondria. A pseudogene of this gene is
	found on chromosome 9. Alternative splicing and the use of multiple translation start codons results
	in multiple transcript variants encoding different isoforms. [provided by RefSeq, Feb 2015]
