Background Histones play a critical role in transcriptional regulation, cell cycle progression, and developmental

events. Histone acetylation/deacetylation alters chromosome structure and affects transcription factor access to DNA. The protein encoded by this gene belongs to class II of the histone

deacetylase/acuc/apha family. It contains an internal duplication of two catalytic domains which

appear to function independently of each other. This protein possesses histone deacetylase activity

and represses transcription. [provided by RefSeq, Jul 2008]
