Background	This gene encodes a subunit of the transcription factor complex nuclear factor-kappa-B (NFkB).
	The NFkB complex is expressed in numerous cell types and functions as a central activator of
	genes involved in inflammation and immune function. The protein encoded by this gene can
	function as both a transcriptional activator or repressor depending on its dimerization partner. The
	p100 full-length protein is co-translationally processed into a p52 active form. Chromosomal
	rearrangements and translocations of this locus have been observed in B cell lymphomas, some of
	which may result in the formation of fusion proteins. There is a pseudogene for this gene on
	chromosome 18. Alternative splicing results in multiple transcript variants. [provided by RefSeq,
