Background	This gene encodes a seven-transmembrane G-protein-coupled receptor. The encoded protein
	responds to signaling through the neurotransmitter serotonin. The mRNA of this gene is subject to
	multiple RNA editing events, where adenosine residues encoded by the genome are converted to
	inosines. RNA editing is predicted to alter the structure of the second intracellular loop, thereby
	generating alternate protein forms with decreased ability to interact with G proteins. Abnormalities
	in RNA editing of this gene have been detected in victims of suicide that suffer from depression. In
	addition, naturally-occuring variation in the promoter and 5' non-coding and coding regions of this
	gene may show statistically-significant association with mental illness and behavioral disorders.
	Alternative splicing results in multiple different transcript variants. [provided by RefSeq, Jan 2015]
