| Background           | Ribosomes, the organelles that catalyze protein synthesis, consist of a small 40S subunit and a       |
|----------------------|---|
|                      | large 60S subunit. Together these subunits are composed of 4 RNA species and approximately 80         |
|                      | structurally distinct proteins. This gene encodes a cytoplasmic ribosomal protein that is a           |
|                      | component of the 40S subunit. The protein belongs to the S6E family of ribosomal proteins. It is the  |
|                      | major substrate of protein kinases in the ribosome, with subsets of five C-terminal serine residues   |
|                      | phosphorylated by different protein kinases. Phosphorylation is induced by a wide range of stimuli,   |
|                      | including growth factors, tumor-promoting agents, and mitogens. Dephosphorylation occurs at           |
|                      | growth arrest. The protein may contribute to the control of cell growth and proliferation through the |
|                      | selective translation of particular classes of mRNA. As is typical for genes encoding ribosomal       |
|                      | proteins, there are multiple processed pseudogenes of this gene dispersed through the genome.         |
